The goal of the GPSTk project is to provide a world class, open source computing suite to the satellite navigation community. It is our hope that the GPSTk will empower its users to perform new research and create new applications.

GPS users employ practically every computational architecture and operating system. Therefore the design of the GPSTk suite is as platform-independent as possible. Platform independence is achieved through use of the ANSI-standard C++ programming language. The principles of object-oriented programming are used throughout the GPSTk code base in order to ensure that the code is modular, extensible and maintainable.

The GPSTk suite consists of a core library and a set of applications. The library provides a wide array of functions that solve processing problems associated with GPS such as processing or using RINEX. The library is the basis for the more advanced applications distributed as part of the GPSTk suite.

The GPSTk is sponsored by Space and Geophysics Laboratory, within the Applied Research Laboratories at the University of Texas at Austin (ARL:UT). GPSTk is the by-product of GPS research conducted at ARL:UT since before the first satellite launched in 1978; it is the combined effort of many software engineers and scientists. In 2003 the research staff at ARL:UT decided to open source much of their basic GPS processing software as the GPSTk.

Part I

Theory

Chapter 1

The Global Positioning System in a Nutshell

The Global Positioning System is actually a U.S. government satellite navigation system that provides a civilian signal. As of this writing, the signal is broadcast simultaneously by a constellation of 29 satellites each with a 12 hour orbit. From any given position on the Earth, 8 to 12 satellites are usually visible at a time.

1.1 GPS in a Nutshell

Each satellite broadcasts spread spectrum signals at 1575.42 and 1227.6 MHz, also known as L1 and L2, respectively. Currently the civil signal is broadcast only on L1. The signal contains two components: a time code and a navigation message. By differencing the received time code with an internal time code, the receiver can determine the distance, or range, that the signal has traveled. This range observation is offset by errors in the (imperfect) receiver clock; therefore it is called a pseudorange. The navigation message contains the satellite ephemeris, which is a numerical model of the satellite's orbit.

GPS receivers record, besides the pseudorange, a measurement called the carrier phase (or just phase); it is also a range observation like the pseudorange, except (1) it has an unknown constant added to it (the phase ambiguity) and (2) it is much smoother (about 100 times less measurement noise than the pseudorange!), which makes it useful for precise positioning. Because of the way it is measured, the phase is subject to random, sudden jumps; these discrete changes always come in multiples of the wavelength of the GPS signal, and are called cycle slips.

1.1.1 The Position Solution

The standard solution for the user location requires a pseudorange measurement and an ephemeris for each satellite in view. At least four measurements are

required as there are four unknowns: 3 coordinates of position plus the receiver clock offset. The basic algorithm for the solution is described in the official GPS Interface Control Document, or ICD-GPS-200. The position solution is corrupted due to two sources of error: errors in the observations and errors in the ephemeris.

Reducing Measurement Errors

The GPS signal travels through every layer of the Earth's atmosphere. Each layer affects the signal differently. The ionosphere, which is the high-altitude, electrically charged part of the atmosphere, introduces a delay, and therefore a range error, into the signal. The delay is frequency dependent, so it can be directly computed if you have data on both the GPS frequencies. There is also a delay due to the troposphere, the lower part of the atmosphere. This delay too can be modeled and removed. There are many other errors associated with the GPS signal: multipath reflections and relativistic effects are two examples.

More precise applications reduce the effect of error sources by a technique referred to as differential GPS (DGPS). By differencing measurements simultaneously collected by the user and a nearby reference receiver, the errors that are common to both receivers (most of them) are removed. The result of DGPS positioning is a position relative to the reference receiver; adding the reference position to the DGPS solution results in the absolute user position.

The alternative to DGPS is to explicitly model and remove errors. Creating new and robust models of phenomena that affects the GPS signal is an area of active research at ARL:UT and other laboratories. The positioning algorithm can be used to explore such models. Essentially, the basic approach is to turn the positioning algorithm inside out to look at the corrections themselves. For example, observations from a network of receivers can create a global map or model of the ionosphere.

Improved Ephemerides

The GPS position solution can be directly improved by using an improved satellite ephemeris. The U.S National Geospatial-Intelligence Agency (NGA) generates and makes publicly available a number of precise ephemerides, which are more accurate satellite orbits. Satellite orbits described by the broadcast navigation message have an error on the order of meters; the precise ephemeris has decimeter accuracy. The International GPS Service (IGS) is a global civil cooperative effort that also provides free precise ephemeris products. Global networks of tracking stations produce the observations that make generation of the precise ephemerides possible.

1.2 GPS Data Sources

GPS observation data from many tracking stations are freely available on the Internet. Many such stations contribute their data to the IGS. In addition,

many networks of stations also post their data to the Internet; for example the Australian Regional GPS Network (ARGN) and global cooperatives such as NASA's Crust Dynamics Data Information System (CDIS).

1.2.1 GPS File Formats

Typically GPS observations are recorded in a standardized format developed by and for researchers. Fundamental to this format is the idea that the data should be independent of the type of receiver that collected it. For this reason the format is called Receiver INdependent Exchange, or RINEX. Another format associated with GPS is SP-3, which records the precise ephemeris. The GPSTk supports both RINEX and SP-3 formats.

1.2.2 Receiver Protocols

GPS receivers have become less expensive and more capable over the years, in particular handheld and mobile GPS receivers. The receivers have many features in common. All of the receivers output a position solution every few seconds. All receivers store a list of positions, called waypoints. Many can display maps that can be uploaded. Many can communicate with a PC or handheld to store information or provide position estimates to plotting software.

Typically communication with a PC and other system follows a standard provided by the National Marine Electronics Association called NMEA-0183. NMEA-0183 defines an ASCII based format for communication of position solutions, waypoints and a variety of receiver diagnostics. Here is an example of a line of NMEA data, or sentence:

```
$GPGLL,5133.81,N,00042.25,W*75
```

The data here is a latitude, longitude fix at 51 deg 33.81 min North, 0 deg 42.25 min West; the last part is a checksum.

As a public standard, the NMEA-0183 format has given the user of GPS freedom of choice. NMEA-0183 is the format most typically used by open source applications that utilize receiver-generated positions.

Closed standards are also common. SiRF is a proprietary protocol that is licensed to receiver manufacturers. Many receiver manufacturers implement their own binary protocols. While some of these protocols have been opened to the public, some have been reverse engineered.

Chapter 3

Converting Coordinates & Time

3.1 Transformations

Let $\mathbf{i}_x, \mathbf{i}_y, \mathbf{i}_z$ and $\mathbf{i}_\varepsilon, \mathbf{i}_\eta, \mathbf{i}_\zeta$ be two sets of orthogonal unit vectors

$$\mathbf{i}_\varepsilon = l_1 \mathbf{i}_x + m_1 \mathbf{i}_y + n_1 \mathbf{i}_z$$

$$\mathbf{i}_\eta = l_2 \mathbf{i}_x + m_2 \mathbf{i}_y + n_2 \mathbf{i}_z$$

$$\mathbf{i}_\zeta = l_3 \mathbf{i}_x + m_3 \mathbf{i}_y + n_3 \mathbf{i}_z$$

$$\begin{bmatrix} x \\ y \\ z \end{bmatrix} = \mathbf{R} \begin{bmatrix} \varepsilon \\ \eta \\ \zeta \end{bmatrix} \text{ or } \begin{bmatrix} \varepsilon \\ \eta \\ \zeta \end{bmatrix} = \mathbf{R}^T \begin{bmatrix} x \\ y \\ z \end{bmatrix}$$

$$\mathbf{R} = \begin{bmatrix} \mathbf{i}_x \cdot \mathbf{i}_\varepsilon & \mathbf{i}_x \cdot \mathbf{i}_\eta & \mathbf{i}_x \cdot \mathbf{i}_\zeta \\ \mathbf{i}_y \cdot \mathbf{i}_\varepsilon & \mathbf{i}_y \cdot \mathbf{i}_\eta & \mathbf{i}_y \cdot \mathbf{i}_\zeta \\ \mathbf{i}_z \cdot \mathbf{i}_\varepsilon & \mathbf{i}_z \cdot \mathbf{i}_\eta & \mathbf{i}_z \cdot \mathbf{i}_\zeta \end{bmatrix} = \begin{bmatrix} l_1 & l_2 & l_3 \\ m_1 & m_2 & m_3 \\ n_1 & n_2 & n_3 \end{bmatrix}$$

$$\mathbf{R}^T = \mathbf{R}^{-1}$$

Equations found here [1, pp. 81-82]

3.2 Time Systems

3.2.1 Solar & Sidereal Time

Since the beginning time has been kept by counting the the days. An apparent solar day is the minimum time elapsed between the sun crossing a specified

meridian and then recrossing the same meridian. This form of time keeping is problematic because no two apparent solar days are of the same duration due to Earth's rotation around the sun as well as around its axis (the Earth does a little more than one rotation per apparent solar day). Also, Earth's rotational speed is not constant and its axis of rotation is tilted 23.5° to the orbital plane. These imperfections call for correction, and thus mean solar time was created. A day in mean solar time is defined as one revolution of a hypothetical sun that orbits at the equator, and is more commonly known as Greenwich Mean Time. Another solution is to base our day on the crossing of a star much farther away thus minimizing the effect of the Earth's orbital movement, this method of time keeping is known as sidereal time. A sidereal day is about 4 minutes shorter than a solar day, and is used heavily by astronomers. Sidereal time is not truly stable either so mean sidereal day was introduced, and is known as Greenwich Apparent Sidereal Time. Universal Time (UT) refers to any time scale based on the Earth's rotation. UT0 refers to the mean solar time at the prime meridian as obtained from astronomical observation, and UT1 is UT0 corrected for polar motion. Briefly ephemeris time was introduced to standardize the second, which was defined as $1/31556925.9747$ of the year 1900. This was soon replaced by atomic time [4, pp. 84-86].

3.2.2 Atomic Time

The second is now defined by an atomic standard that is based on the resonance frequency of the cesium atom. To be precise, the second is defined as "9,192,631,770 periods of the radiation corresponding to the transition between the two hyperfine levels of the ground state of the cesium-133 atom," whose duration happens to exactly match the ephemeris second discussed in the previous section. The problem with detaching our time keeping method from the Earth is that as the Earth slows its rotation noon will move closer to midnight (over the duration of thousands of years, of course). Coordinated Universal Time (UTC) was introduced to prevent this. UTC is a compromise between the precision of atomic time and the groundedness of Earth based time keeping, it uses the atomic second but introduces leap seconds (positive or negative) when necessary to keep UTC within .9 seconds of UT1 [4, pp. 86-87].

3.2.3 Time Formats

We are used to dealing with months, days, years, hours, minutes, and seconds, but such a time format makes for difficult epoch calculations over long periods. To solve this problem Julian Date (JD) was introduced. JD consists of a day count (days since noon UT on January 1st 4713 B.C.) and a fraction of the current day. This makes for easy time differencing, but the length of the date can become cumbersome and the fact that a new day starts at noon confusing. To make things even easier Modified Julian Date (MJD) was created whos origin

is midnight November 17th, 1858.

$$\text{MJD} = \text{JD} - 2400000.5$$

In order to make Julian Date useful we need an easy way to go between calendar dates and JD. *timeconvert* does this and more with ease. The equations to convert from calendar date to JD are

$$\text{JD} = \text{INT}[365.25y] + \text{INT}[30.6001(m+1)] + D + \text{UT}/24 + 1720981.5$$

$$\begin{aligned} y &= Y - 1 & \text{and } m &= M + 12 & \text{if } M \leq 2 \\ y &= Y & \text{and } m &= M & \text{if } M > 2 \end{aligned}$$

where M is the month, D is the day, Y is the year, and $\text{INT}[x]$ returns just the integer part of the a number. To go from JD to calendar date

$$a = \text{INT}[\text{JD} + 0.5]$$

$$b = a + 1537$$

$$c = \text{INT}[(b - 122.1)/365.25]$$

$$d = \text{INT}[365.25c]$$

$$e = \text{INT}[(b - d)/30.6001]$$

$$D = b - d - \text{INT}[30.6001e] + \text{FRAC}[\text{JD} + 0.5]$$

$$M = e - 1 - 12\text{INT}[e/14]$$

$$Y = c - 4715 - \text{INT}[(7 + M)/10]$$

where $\text{FRAC}[x]$ returns just the fractional part of a real number. MJD Conversion found here [4, p. 88]. All other date conversions were found here [2, pp. 36-37]

3.2.4 GPS Time

GPS Time (GPST) is a continuously running composite time kept by cesium and rubidium frequency standards aboard the satellites and at monitor stations. While there are no leap seconds in GPST as there are in UTC, it is steered to stay within 1 μs of UTC, that is the difference between GPST and UTC is an integer number of seconds plus a fraction of a μs . GPST is formatted in terms of GPS weeks and the number of seconds into the current week. Finding these values is done easily if the Julian Date is known.

$$\text{GPS WEEK} = \text{INT}[(\text{JD} - 2444244.5)/7]$$

$$\text{SOW} = \text{FRAC}[(\text{JD} - 2444244.5)/7] \times 604800$$

where $\text{INT}[x]$ returns the integer part of a real number, $\text{FRAC}[x]$ returns the fractional part, and SOW stands for Second of Week.

Other useful quantities such as Day of Week and Second of Day can be found using *timeconvert* or the following equations.

$$\text{DOW} = \text{modulo}\{\text{INT}[\text{JD} + 0.5], 7\}$$

$$\text{SOD} = \text{modulo}\{\text{FRAC}[\text{JD} + 0.5], 7\} \times 86400$$

where DOW=0 corresponds to Monday, DOW=1 corresponds to Tuesday, and so on.

JD and GPS Week equations were found here [2, pp. 36-37], SOD derived from DOW equation

3.2.5 Z-Count

Satellites keep internal time with Z-count, whose epoch period is 1.5 seconds (a convenient unit for communications timing). The full Z-count is 29 bits, the 10 bit GPS week folloed by a 19 bit Time of Week (TOW) expressed in Z-counts (or 1.5 second units). The truncated Z-count has a 17 bit TOW that is expressed in units of 6 seconds, or the length of one subframe's transmission time. Simply multiply the truncated TOW by 4 to get the full TOW [5, pp. 86-88].

$$\text{TOW} = \text{FRAC}[(\text{JD} - 2444244.5)/7] \times 403200$$

$$\text{Truncated TOW} = \text{FRAC}[(\text{JD} - 2444244.5)/7] \times 100800$$

Equations derived from SOW equation above

3.3 Earth Fixed Coordinates

3.3.1 ECI to ECF

$$\begin{bmatrix} x \\ y \\ z \end{bmatrix}_{ECF} = T_{XYZ}^{xyz} \begin{bmatrix} X \\ Y \\ Z \end{bmatrix}_{ECI}$$

$$T_{XYZ}^{xyz} = WSNP$$

P - applies precession, from epoch 2000.0 to the current time; N - applies nutation, from epoch 2000.0 to the current time; S - applies rotation to account for true sidereal time; W - applies polar motion;

Equations found on page 85 of Fundamentals of Orbit Determination paper book

3.3.2 WGS-84

The World Geodetic System 1984 (WGS-84) is fixed physical model of Earth produced by the Department of Defense to which many different reference frames can be attached. WGS-84 consists of two parts, a model of Earth's gravitational field, and an ellipsoid describing the Earth's general shape. When dealing with locations on the Earth's surface the ellipsoid provides the foundation for the geodetic coordinate system used by GPS. The ellipsoid's cross-sections parallel to the equatorial plane are circular while those orthogonal are elliptical. The ellipses are parameterized by an eccentricity e , a flattening f , and sometimes a second eccentricity e'

$$e = \sqrt{1 - \frac{b^2}{a^2}}$$

$$f = 1 - \frac{b}{a}$$

$$e' = \sqrt{\frac{a^2}{b^2} - 1} = \frac{a}{b}e$$

where a , the semimajor axis, is the value of the mean equatorial radius of Earth (6,378.137 km) and b , the semiminor axis, is the value of the polar radius of Earth (6,356.7523142 km) [3, pp. 25-26].

3.3.3 Coordinate Systems

Now that WGS-84 is defined it is important to understand what coordinate systems can be attached to the ellipsoid and how to move between these different systems. The GPS Toolkit comes with *poscvt*, an application that gives users the ability to easily convert coordinates in one reference frame to another. The coordinate systems that *poscvt* recognizes are Cartesian (or XYZ), geodetic, geocentric, and spherical coordinates. These systems and the formulas to convert between them are discussed below.

Cartesian (XYZ) Coordinates

The Earth Centered Earth Fixed (ECEF) Cartesian coordinate system is fixed to the WGS-84 ellipsoid and is the common ground that makes going between the Earth Centered Inertial (ECI) reference frame used by the satellites and the systems we are used to (such as latitude, longitude, and height) manageable. The equatorial plane makes the xy -plane with the $+x$ -axis pointing toward 0° longitude and the $+y$ -axis pointing toward 90° E longitude. The z -axis is normal to the equatorial plane and points to the geographical north pole. The conversion formulas presented in the next sections will convert to and from this Cartesian reference frame, and so to convert between two non-Cartesian coordinate systems the XYZ system will be used as an intermediary [3, p. 24].

Geodetic Coordinates

The geodetic coordinate parameters are longitude λ , latitude ϕ , and height h . Longitude is defined as the angle between the position and the x -axis in the equatorial plane, and is easily computed given a position in Cartesian coordinates. Let a user's position $\mathbf{U} = (x_u, y_u, z_u)$, then

$$\lambda = \begin{cases} \arctan\left(\frac{y_u}{x_u}\right), & x_u \geq 0 \\ 180^\circ + \arctan\left(\frac{y_u}{x_u}\right), & x_u < 0 \text{ and } y_u \geq 0 \\ -180^\circ + \arctan\left(\frac{y_u}{x_u}\right), & x_u < 0 \text{ and } y_u < 0 \end{cases}$$

where negative angles signal west longitude.

Latitude and height are not so straight forward. Latitude is determined by drawing a vector normal to the ellipsoid, beginning somewhere on the equatorial plane and terminating at the users position, we will call this the user vector. The smallest angle between this vector and the equatorial plane is the user's latitude, it is a North latitude for positive angles and South for negative. Notice that unless the user is at a pole or on the equator the vector does not pass through the center of the Earth. The users height is found by taking the magnitude of the vector originating on and normal to the ellipsoid and terminating at the user's position. Latitude ϕ and height h are found using the following equations

$$\phi = \arctan\left(\frac{z_u + e'^2 z_0}{r}\right)$$

$$h = U\left(1 - \frac{b^2}{aV}\right)$$

where

$$r = \sqrt{x_u^2 + y_u^2}$$

$$E^2 = a^2 - b^2$$

$$F = 54b^2 z_u^2$$

$$G = r^2 + (1 - e^2)z_u^2 - e^2 E^2$$

$$c = \frac{e^4 F r^2}{G^3}$$

$$s = \sqrt[3]{1 + c + \sqrt{c^2 + 2c}}$$

$$P = \frac{F}{3\left(s + \frac{1}{s} + 1\right)^2 G^2}$$

$$Q = \sqrt{1 + 2e^4 P}$$

$$\begin{aligned}
r_0 &= -\frac{Pe^2r}{1+Q} + \sqrt{\frac{1}{2}a^2 \left(1 + \frac{1}{Q}\right) - \frac{P(1-e^2)z_u^2}{Q(1+Q)} - \frac{1}{2}Pr^2} \\
U &= \sqrt{(r - e^2r_0)^2 + z_u^2} \\
V &= \sqrt{(r - e^2r_0)^2 + (1 - e^2)z_u^2} \\
z_0 &= \frac{b^2z_u}{aV}
\end{aligned}$$

Going back to Cartesian coordinates from the geodetic system $(\lambda \ \phi \ h)$ can be done more compactly

$$\mathbf{u} = \begin{bmatrix} \frac{a \cos \lambda}{\sqrt{1+(1-e^2)\tan^2 \phi}} + h \cos \lambda \cos \phi \\ \frac{a \sin \lambda}{\sqrt{1+(1-e^2)\tan^2 \phi}} + h \sin \lambda \cos \phi \\ \frac{a(1-e^2)\sin \phi}{\sqrt{1-e^2 \sin^2 \phi}} + h \sin \phi \end{bmatrix}$$

where \mathbf{u} is the user's position vector [3, 4, pp. 26-28, p. 76].

Geocentric Coordinates

$$\begin{aligned}
x &= r \cos \phi \cos \lambda \\
y &= r \cos \phi \sin \lambda \\
z &= r \sin \phi
\end{aligned}$$

where λ and ϕ are geocentric longitude and latitude

found on page 82 in the Fundamentals of Orbital Determination paper book

Spherical Coordinates

Topocentric Coordinates

$$\mathbf{r}_t = T_t(\mathbf{r} - \mathbf{r}_s) = T_t \rho$$

\mathbf{r} and \mathbf{r}_s are the position vectors of the observer and satellite respectively in the Earth-fixed system

$$T_t = \begin{bmatrix} -\sin \lambda & \cos \lambda & 0 \\ -\sin \phi \cos \lambda & -\sin \phi \sin \lambda & \cos \phi \\ \cos \phi \cos \lambda & \cos \phi \sin \lambda & \sin \phi \end{bmatrix}$$

where λ and ϕ are geocentric longitude and latitude

found on page 84 in the Fundamentals of Orbital Determination paper book to find *azimuth* (Az) and *elivation* (El)

$$\begin{aligned}
\sin \text{El} &= \frac{z_t}{r_t} & -90^\circ \leq \text{El} \leq 90^\circ \\
\sin \text{Az} &= \frac{x_t}{r_{xy}} \\
\cos \text{Az} &= \frac{y_t}{r_{xy}} & 0^\circ \leq \text{Az} \leq 360^\circ
\end{aligned}$$

Equations found on pages 84-85 in Fundamentals of Orbit Determination paper book

Part II

Usage, Examples & Notes

	Tool	Description	Execution Example
Transforms	calgps	generates a GPS calendar	calgps -Y 2004
	poscv	converts a given input position to other position formats	poscv --geodetic="30.28 262.26700 167.64"
	timeconvert	converts given input time to other time formats	timeconvert --calendar="07 04 2006"
	WhereSat	outputs expected location of a satellite	WhereSat -b arl2100.06n -p 3
Collecting & Converting	rtAshtech	records observations from an Ashtech receiver	rtAshtech -p /dev/ttyS1 -o "minute%03j%02H%02m.%06yo"
	ficfca ficafic fic2rin	convert fic files between ASCII, binary, and Rinex formats	fic2rin fic2100.06 rin121.06n
	mdp2fic mdp2rinex	convert MDP files to fic or rinex files	mdp2rinex -i mdpfile -o arl2100.06o
	novaRinex	convert Novatel files to Rinex files	novaRinex --input nova2100.06 --obstype L1
	navdmp	dumps information from nav files to human readable formats	navdmp -i arl2100.06n -o arl2100.06.dmp
	RinexDump	dumps observation data for specified satellites from a Rinex file	RinexDump arl2100.06o 3 4 L1 L2
Comparing & Validating	ephdiff	compares the satellite positions from two ephemeris sources	ephdiff arl2100.06n fic2100.06
	ficdiff	compares contents of two FIC files	ficidff fic12100.06 fic22100.06
	ficcheck ficacheck	reads a FIC file and checks it for errors reporting the first found	ficcheck fic2100.06 -t "07/20/2006 11:00:00"
	row/rnw/rmwdiff	compares contents of two RINEX files	rowdiff arl1210.06o arl22100.06o
	row/rnw/rmwcheck	read Rinex files and checks it for errors reporting the first found	rnwcheck arl210.06n -e "07/20/2006 11:00:00"
	navsum RinSum	summarizes the contents of nav/Rinex files	RinSum -i arl2100.06o --EpochBeg 2006,07,20,13,20,00
	mdptool	manipulates MDP data streams	mdptool -i mdpfile --pvt --obs
Editing Data	reszilla	computes various residuals from GPS data	reszilla -o arl210.06o -e arl2100.06n
	mergeFIC	sorts and merges input FIC files into a single file	mergeFIC -i fic12100.06 -i fic22100.06 -o ficmerge2100.06
	mergeRinObs/Nav/Met	sorts and merges RINEX files	mergeRinNav -i arl2100.06n -i arl2110.06n arl210-211.06n
	NavMerge	merges Rinex nav files into a single file	NavMerge -o arlnavs.06n arl2100.06n arl2110.06n
	rinexthin	decimates an input Rinex observation files to desired data rate	rinexthin -f arl2100.06o -s 30 -o arl2100thin.06n
	ResCor	edits Rinex files and computes corrections	ResCor -IFalr2100.06o -0Farl2100mod.06o -DS12,12:00:00
	DiscFix	cycle slip corrector	DiscFix -i arl2100.06o --DT 1.5
Iono	IonoBias	solves interfrequency biases and a simple ionosphere model	IonoBias --input arl2100.06o --nav arl2100.06n --XSat 3
	TECMaps	creates maps of Total Electron Content (TEC)	TECMaps --input arl2100.06o --nav arl2100.06n --LinearFit
Positioning	PRSolve	generates autonomous position solution	PRSolve -o alr2100.06o -n arl2100.06nn --XPRN 12
	rinexpvt	generates autonomous position solution	rinexpvt -o alr2100.06o -n arl2100.06n
	DDBase	computes a network solution using carrier phase	DDBase ... --ObsFile arl2100.06o --PosXYZ x,y,z,1 --Fix
	vecsol	estimates short baseline using range or carrier phase	vecsol station12100.06o station22100.06o

Table 3.0: GPSTk Applications at a Glance

3.5 *calgps*

3.5.1 Overview

This application generates a dual GPS and Julian calendar. The arguments and format are inspired by the UNIX 'cal' utility. With no arguments, the current argument is printed. The last and next month can also be printed. Also, the current or any given year can be printed.

3.5.2 Usage

Optional Arguments

Short Arg.	Long Arg.	Description
-h	-help	Generates help output.
-3	-three-months	Prints a GPS calendar for the previous, current, and next month.
-y	-year	Prints a GPS calendar for the entire current year.
-Y year	-specific-year=NUM	Prints a GPS calendar for the entire specified year.

3.5.3 Examples

```
> calgps -3
```

```

                        Jul 2006
1381                                1-182

.	.	.					

3.5.4 Notes

If multiple options are given only the first is considered.

3.6 *fic2rin*

3.6.1 Overview

This application converts navigation messages between the FIC format, a format for GPS observations established by ARL:UT, and the RINEX format.

3.6.2 Usage

```
fic2rin usage: fic2rin <input FIC file> <output RINEX file name>
```

3.6.3 Examples

```
> fic2rin fic06.187 rin1870.06
```

File Snippets

Binary FIC File

```
00000000

```

3.6.4 Notes

3.7 *ficacheck ficcheck*

3.7.1 Overview

The application reads input FIC files and checks them for errors.

3.7.2 Usage

Optional Arguments

Short Arg.	Long Arg.	Description
-d	-debug	Increase debug level
-v	-verbose	Increase verbosity
-h	-help	Print help usage
-t	-time=TIME	Time of first record to count (default = "beginning of time")
-e	-end-time=TIME	End of time range to compare (default = "end of time")

```
ficacheck usage: ficacheck [options] <FICA file>
```

```
ficcheck usage: ficcheck [options] <FIC file>
```

3.7.3 Examples

```
> ficcheck fic06.187
```

```
Checking fic06.187
```

```
Read 252 records.
```

```
> ficacheck brokenfica
```

```
Checking brokenfica
```

```
text 0:Bad block header, record=2 location=484
```

```
text 1:blkHdr=[ ]
```

```
text 2:In record 2
```

```
text 3:In file brokenfica
```

```
text 4:Near file line 10
```

```
location 0:src/FICData.cpp:926
```

```
location 1:src/FFStream.cpp:125
```

```
location 2:src/FFStream.hpp:172
```

```
location 3:src/FFStream.hpp:172
```

3.7.4 Notes

Only the first error in each file is reported. The entire file is always checked regardless of time options.

3.8 *ficafic ficfica*

3.8.1 Overview

These applications convert navigation message data between variations of the FICformat, a format for GPS observations established by ARL:UT.

3.8.2 Usage

```
ficafic usage: ficafic <input fica file> <output fic file name>
ficfica usage: ficfica <input fic file> <output fica file name>
```

3.8.3 Examples

```
> ficfica fic06.187 fica06.187
```

File Snippets

Binary FIC File

```

3.8.4 Notes

3.9 *ficdiff*

3.9.1 Overview

The application compares the contents of two FIC files containing ephemeris data.

3.9.2 Usage

Optional Arguments

Short Arg.	Long Arg.	Description
-d	-debug	Increase debug level
-v	-verbose	Increase verbosity
-h	-help	Print help usage
-t	-time=TIME	Start of time range to compare (default = "beginning of time")
-e	-end-time=TIME	End of time range to compare (default = "end of time")

ephdiff usage: ficdiff [options] fic1 fic2

3.9.3 Examples

```
> ficdiff -t "08/01/2006 12:00:00" fic1 fic2
<FIC BlockNumber: 9
floats: 139 362 172806 1 1 1386 1 0 0 55296 0 -4.19095e-09 180000 0 . . .

```

3.9.4 Notes

3.10 *mdp2fic mdp2rinex*

3.10.1 Overview

The applications convert a variety of GPS related observations from the MDP format to FIC and RINEX formats. MDP is a format for network receiver interfaces derived by ARL:UT that can be used to serve observations over networks.

3.10.2 Usage

<i>mdp2fic</i>		
Required Arguments		
Short Arg.	Long Arg.	Description
-i	-mdp-input=ARG	Filename to read MDP data from. The filename of '-' means to use stdin.
-n	-nav=ARG	Filename to which FIC nav data will be written.
Optional Arguments		
Short Arg.	Long Arg.	Description
-d	-debug	Increase debug level
-v	-verbose	Increase verbosity
-h	-help	Print help usage
-l	-log=ARG	Filename for (optional) output log file

<i>mdp2rinex</i>		
Required Arguments		
Short Arg.	Long Arg.	Description
-i	-mdp-input=ARG	Filename to read MDP data from. The filename of '-' means to use stdin.
-n	-obs=ARG	Filename to write RINEX obs data to. The filename of '-' means to use stdout.
Optional Arguments		
Short Arg.	Long Arg.	Description
-d	-debug	Increase debug level
-v	-verbose	Increase verbosity
-h	-help	Print help usage
-n	-nav=ARG	Filename to write RINEX nav data to.
-t	-thinning=ARG	A thinning factor for the data, specified in seconds between points. Default: none.
-c	-l2c=ARG	Enable output of L2C data in C2.

3.10.3 Examples

```
> mdp2fic -i mdp183.06 -o fic183.06 -l mdp2ficlog183.06
```

```
> mdp2rinex -i mdp183.06 -o rin183.06o -n rin183.06n -t 60
```

3.10.4 Notes

3.11 *mdptool*

3.11.1 Overview

The application performs various functions on a stream of MDP data.

3.11.2 Usage

Optional Arguments		<i>mdptool</i>
Short Arg.	Long Arg.	Description
-d	-debug	Increase debug level
-v	-verbose	Increase verbosity
-h	-help	Print help usage
-i	-input=ARG	Where to get the MDP data from. The default is to use stdin. If the file name begins with "tcp:" the remainder is assumed to be a hostname[:port] and the source is taken from a tcp socket at this address. If the port number is not specified a default of 8910 is used.
	-output=ARG	Where to send the output. The default is stdout.
-p	-pvt	Enable pvt output
-o	-obs	Enable obs output
-n	-nav	Enable nav output
-t	-test	Enable selftest output
-x	-hex	Dump all messages in hex
-b	-bad	Try to process bad messages also.
-a	-almanac	Build and process almanacs. Only applies to the nav style
-e	-ephemeris	Build and process engineering ephemerides. Only applies to the nav style
-s	-output-style=ARG	What type of output to produce from the MDP stream. Valid styles are: brief, verbose, table, track, null, mdp, nav, and summary. The default is summary. Some modes aren't quite complete. Sorry.
-l	-timeSpan=NUM	How much data to process, in seconds
	-startTime=TIME	Ignore data before this time. (%4Y/%03j/%02H:%02M:%05.2f)
	-stopTime=TIME	Ignore any data after this time

3.11.3 Examples

3.11.4 Notes

In the summary mode, the default is to only summarize the obs data above 10 degrees. Increasing the verbosity level will also summarize the data below 10 degrees.

3.12 *mergeRinObs mergeRinNav mergeRinMet mergeFic*

3.12.1 Overview

The applications merge multiple RINEX observation, navigation, or meteorological data files into a single coherent RINEX obs/nav/met file.

3.12.2 Usage

Required Arguments		<i>mergeRinObs</i>
Short Arg.	Long Arg.	Description
-i	-input=ARG	An input RINEX Obs file, can be repeated as many times as needed.
-o	-output=ARG	Name for the merged output RINEX Obs file. Any existing file with that name will be overwritten.
Optional Arguments		
Short Arg.	Long Arg.	Description
-d	-debug	Increase debug level
-v	-verbose	Increase verbosity
-h	-help	Print help usage

mergeRinNav and *mergeRinNav* have the same usage.

3.12.3 Examples

```
> mergeRinObs -i arl280.06o -i arl2810.06o -o arl280-10.06o
```

```
> mergeRinNav -i arl280.06n -i arl2810.06n -o arl280-10.06n
```

```
> mergeRinMet -i arl280.06m -i arl2810.06m -o arl280-10.06m
```

3.12.4 Notes

3.13 *navdmp*

3.13.1 Overview

The application prints the contents of an FIC or RINEX file into a human readable file and allows filtering of the data.

3.13.2 Usage

<i>navdmp</i>		
Required Arguments		
Short Arg.	Long Arg.	Description
-i	-input=ARG	Name of an input navigation message file
-o	-output=ARG	Name of an output file
Optional Arguments		
Short Arg.	Long Arg.	Description
-d	-debug	Increase debug level
-v	-verbose	Increase verbosity
-h	-help	Print help usage
-a	-all-records	Unless otherwise specified, use default values for record filtration.
-t	-time=TIME	Start time (of data) for processing
-e	-end-time=TIME	End time (of data) for processing
-p	-prn=NUM	PRN(s) to include
-b	-block=NUM	FIC block number(s) to process ((9)109 (Engineering) ephemerides, (62)162 (engineering) almanacs)
-r	-RINEX	Assume input file is a RINEX navigation message file

3.13.3 Examples

```
> bash-3.00$ navdmp -i algo1720.06n -o summary !!!!!WHAT ON EARTH-t "06/25/2006 10:30:00"!!!! -p 1 -p 2 -r

Current filtering options:
  Start time: 01/10/0006 16:09:24
  End time:   01/01/4713 00:00:00
  PRNs:       1 2

Choose an option by number then push enter:
  1) Change the start time
  2) Change the end time
  3) Select specific PRNs
  5) Process the file
use ctrl-c to exit
? 5

processing...

3.13.4 Notes

3.14 *poscv*t

3.14.1 Overview

This application allows the user to convert among different coordinate system on the command line. Coordinate systems handled include Cartesian, geocentric, and geodetic.

3.14.2 Usage

Optional Arguments

Short Arg.	Long Arg.	Description
-d	-debug	Increase debug level
-v	-verbose	Increase verbosity
-h	-help	Print help usage
	-ecef=POSITION	ECEF "X Y Z" in meters
	-geodetic=POSITION	Geodetic "lat lon alt" in deg, deg, meters
	-geocentric=POSITION	Geocentric "lat lon radius" in deg, deg, meters
	-spherical=POSITION	Spherical "theta, pi, radius" in deg, deg, meters
-l	-list-formats	List the available format codes for use by the input and output format options.
-F	-output-format=ARG	Write the position with the given format

3.14.3 Examples

```
> poscv --ecef="-4346070.69263 4561978.26297 803.498856837"
```

```
ECEF (x,y,z) in meters      -4346070.6926 4561978.2630 803.4989
Geodetic (llh) in deg, deg, m 0.00735641 133.61157352 -77345.2412
Geocentric (llr) in deg, deg, m 0.00730656 133.61157352 6300791.7584
Spherical (tpr) in deg, deg, m 89.99269344 133.61157352 6300791.7584
```

```
> poscv -l
```

```
%X %Y %Z (cartesian or ECEF in kilometers)
%x %y %z (cartesian or ECEF in meters)
%a %l %r (geocentric lat,lon,radius, longitude E, radius in meters)
%A %L %h (geodetic lat,lon,height, longitude E, height in meters)
%a %w %R (geocentric lat,lon,radius, longitude W, radius in kilometers)
%A %W %H (geodetic lat,lon,height, longitude W, height in kilometers)
%t %p %r (spherical theta, phi, radius, degrees and meters)
%T %P %R (spherical theta, phi, radius, radians and kilometers)
```

```
> poscv --ecef="-4346070.69263 4561978.26297 803.498856837" -F "%A %L %h"
\0.007356 \133.611574 \-77345.241247
```

3.14.4 Notes

3.15 *PRsolve*

3.15.1 Overview

The application reads one or more Rinex observation files, plus one or more navigation (ephemeris) files, and computes an autonomous pseudorange position solution, using a RAIM-like algorithm to eliminate outliers. Output is to the log file, and also optionally to a Rinex obs file with the position solutions in auxiliary header blocks.

3.15.2 Usage

Required Arguments		<i>navdmp</i>
Short Arg.	Long Arg.	Description
-o	-obs	Input Rinex observation file(s)
-n	-nav	Input navigation (ephemeris) file(s) (Rinex or SP3)
Optional Arguments: Input		
-f		File containing more options
	-obsdir	Directory of input observation file(s)
	-navdir	Directory of input navigation file(s)
	-decimate	Decimate data to time interval dt
	-EpochBeg	Start time, arg is of the form YYYY,MM,DD,HH,Min,Sec
	-GPSTBeg	Start time, arg is of the form GPSweek,GPSsow
	-EpochEnd	End time, arg is of the form YYYY,MM,DD,HH,Min,Sec
	-GPSEnd	End time, arg is of the form GPSweek,GPSsow
	-CA	Use C/A code pseudorange if P1 is not available
Optional Arguments: Configuration		
	-RMSlimit	Upper limit on RMS post-fit residuals (m) for a good solution
	-SlopeLimit	Upper limit on RAIM 'slope' for a good solution
	-Algebra	Use algebraic algorithm (otherwise linearized LS)
	-DistanceCriterion	Use distance from a priori as convergence criterion (else RMS)
	-ReturnAtOnce	Return as soon as a good solution is found
	-NReject	Maximum number of satellites to reject
	-NIter	Maximum iteration count (linearized LS algorithm)
	-Conv	Minimum convergence criterion (m) (LLS algorithm)
	-MinElev	Minimum elevation angle (deg) (only if -PosXYZ)
	-XPRN	Exclude this satellite.
	-Trop <model,T,P,H>	Trop model (one of BL,SA,NB,GG,GGH (cf.GPSTk)), with OPTIONAL weather Temp(C),Press(mb),RH(%)
Optional Arguments: Output		
	-Log	Output log file name (prs.log).
	-PosXYZ <X,Y,Z>	Known position (ECEF,m), used to compute output residuals.

-APSout	Output autonomous pseudorange solution (APS - no RAIM)
-TimeFormat	Output time format (ala DayTime) (default: %4F %10.3g)

Optional Arguments: RINEX Output

-RinexFile	Output Rinex obs file name
-RunBy	Output Rinex header 'RUN BY' string
-Observer	Output Rinex header 'OBSERVER' string
-Agency	Output Rinex header 'AGENCY' string
-Marker	Output Rinex header 'MARKER' string
-Number	Output Rinex header 'NUMBER' string

Optional Arguments: Help

-verbose	Print extended output.
-debug	Print very extended output.
-h	Print syntax and quit.

3.15.3 Examples

```

3.15.4 Notes

3.16 *reszilla*

3.16.1 Overview

3.16.2 Usage

Required Arguments

Short Arg.	Long Arg.	Description
-o	-obs1=ARG	Observation data file name. If this option is specified more than once the contents of all files will be used.

Optional Arguments

Short Arg.	Long Arg.	Description
-h	-help	Generates help and usage.
-2	-position=ARG	Second receiver's observation data file name. Only used when computing a double difference. If this option is specified more than once the contents of all the files will be used.
	-msc=ARG	Station coordinate file.
-e	-ephemeris=ARG	Ephemeris data file name (either broadcast in RINEX nav, broadcast in FIC, or precise in SP3).
-w	-weather	Weather data file name (RINEX met format only).
-n	-search-near	Use BCEphemeris.searchNear()
-c	-clock-from-rinex	Use the receiver clock offset from the rinex obs data.
	-svtime	Observation data is in SV time frame. The default is RX time frame.
	-check-obs	Report data rate, order of data, data present, data gaps.
	-keep-unhealthy	Keeps unhealthy SVs in the statistics, default is to toss.
-s	-no-stats	Don't compute & output the statistics.
	-cycle-slips	Output a list of cycle slips.
-r	-raw-output=ARG	Dump the computed residuals/ords into specified file. If '-' is given as the file name, the output is sent to standard output. The default is to not output the raw residuals.
	-start-time=TIME	Ignore obs data prior to this time in the analysis. The time is specified using the format %4Y/%03j/%02H:%02M:%05.2f. The default value is to start with the first data found.
	-stop-time=TIME	Ignore obs data after to this time in the analysis. The time is specified using the format %4Y/%03j/%02H:%02M:%05.2f. The default value is to process all data.
-t	-time-format=ARG	Daytime format specifier used for the timestamps in the raw output. The default is "%Y %3j %02H:%02M:%04.1f". If this option is specified with the format as "s", the format "%Y %3j %7.1s" is used. If this option is specified with the format as "s", the format "%Y %3j %02H:%02M:%02S" is used.
	-omode=ARG	ORD mode: P1P2, C1P2, C1, P1, P2. The default is p1p2

	-clock-est	Compute a linear clock estimate.
	-ddmode=ARG	Double difference residual mode: none, sv, or c1p2. The default is sv.
	-min-arc-time=ARG	The minimum length of time (in seconds) that a sequence of observations must span to be considered as an arc. The default value is 60.0 seconds.
	-min-arc-gap=ARG	The minimum length of time (in seconds) between two arcs for them to be considered separate arcs. The default value is 60.0 seconds.
	-min-arc-length=NUM	The minimum number of epochs that can be considered an arc. The default value is 5 epochs.
-b	-elev-bin=ARG	A range of elevations, used in computing the statistical summaries. Repeat to specify multiple bins. The default is "-b 0-10 -b 10-20 -b 20-60 -b 60-90".
	-sigma=NUM	Multiplier for sigma stripping used in computation of statistics on the raw residuals. The default value is 6.
-v	-verbosity=NUM	How much detail to provide about intermediate steps.
	0	nothing but the results
	1	Output status before potentially time consuming operations (default)
	2	more details about each step and the options chosen
	3	add the reasons for editing data
	4	dump intermediate values for each epoch (can be QUITE verbose)

Types in the raw output files:

- 0 - c1p2 observed range deviation
- 50 - computed clock, difference from estimate, strip
- 51 - linear clock estimate, abdev

Double difference types:

- 10 - c1 20 - c2
- 11 - p1 21 - p2
- 12 - l1 22 - l2
- 13 - d1 23 - d2
- 14 - s1 24 - s2

3.16.3 Examples

```
reszilla --omode=p1 --svtime --msc=mscoords.cfg -m 85401 -o asm2004.138 -e s011138a.04n
```

3.16.4 Notes

The criteria min-arc-time and min-arc-length are both required to be met for an arc to be valid in double difference mode. All output quantities (stddev, min, max, ord, clock, double difference, ...) are in meters.

3.17 *rmwcheck rnwcheck rowcheck*

3.17.1 Overview

The applications read a RINEX observation, navigation, or meteorological data file and check it for errors.

3.17.2 Usage

Optional Arguments

Short Arg.	Long Arg.	Description
-d	-debug	Increase debug level
-v	-verbose	Increase verbosity
-h	-help	Print help usage
-t	-time=TIME	Time of first record to count (default = "beginning of time")
-e	-end-time=TIME	End of time range to compare (default = "end of time")

rmwcheck usage: rmwcheck [options] <RINEX Met file>

rnwcheck usage: rnwcheck [options] <RINEX Nav file>

rowcheck usage: rowcheck [options] <RINEX Obs file>

3.17.3 Examples

3.17.4 Notes

Only the first error in each file is reported. The entire file is always checked regardless of time options.

3.18 *RinexDump*

3.18.1 Overview

The application reads a RINEX file and dumps the observation data for the given satellite(s) to the standard output.

3.18.2 Usage

RinexDump usage: RinexDump [-n] <\$rinex file\$> [<satellite(s)> <\$obstype(s)>]

The optional argument -n tells RinexDump its output should be purely numeric.

3.18.3 Examples

```
> RinexDump algo1580.06o 3 4 5

# Rinexdump file: algo1580.06o Satellites: G03 G04 G05 Observations: ALL
# Week GPS_sow Sat      L1 L S      L2 L S      C1 L S

. . .
```

3.18.4 Notes

MATLAB and Octave can read the purely numeric output.

3.19 *rinexpvt*

3.19.1 Overview

The application generates a user position based on RINEX observation data with the option of including navigation and meteorological data to aid error correction.

3.19.2 Usage

Required Arguments		
Short Arg.	Long Arg.	Description
-o	-obs-file=ARG	RINEX obs file
Optional Arguments		
Short Arg.	Long Arg.	Description
-d	-debug	Increase debug level
-v	-verbose	Increase verbosity
-h	-help	Print help usage
-n	-nav-file=ARG	RINEX Nav file. Required for single frequency ionosphere correction.
-p	-pe-file=ARG	SP3 Precise Ephemeris File. Repeat this for each input file.
-m	-met-file=ARG	RINEX Met File
-t	-time-format=ARG	Alternate time format string.
-e	-enu=ARG	Use the following as origin to solve for East/North/Up coordinates, formatted as a string: "X Y Z"
-l	-elevation-mask=ARG	Elevation mask (degrees)
-s	-single-frequency	Use only C1 (SPS)
-f	-dual-frequency	Use only P1 and P2 (PPS)
-i	-no-ionosphere	Do NOT correct for ionosphere delay.
-x	-no-closest-ephemeris	Allow ephemeris use outside of fit interval.
-c	-no-carrier-smoothing	Do NOT use carrier phase smoothing.

3.19.3 Examples

```
> rinexpvt -o arl2800.06o -n arl2800.06n

```

3.19.4 Notes

Though not stated in the required options lists either a RINEX navigation file or an SP3 Precise Ephemeris File is needed, using the -n or -p option respectively. When using precise ephemeris 3 files must be included, the previous day's, the current day's and the next day's.

3.20 *rinexthin*

3.20.1 Overview

This application decimates an input RINEX observation file to a specified data rate.

3.20.2 Usage

Required Arguments		
Short Arg.	Long Arg.	Description
-f	-filename=ARG	RINEX obs file to be thinned.
-s	-Seconds=NUM	The desired data rate.
-o	-filename=ARG	RINEX obs file with thinned obs.

navdmp

3.20.3 Examples

```
> rinexthin -f arl2800.06o -s 60 -o arl2800thin.06o
```

```
Obs read: 2880
Obs written: 1440
```

3.20.4 Notes

3.21 *rtAshtech*

3.21.1 Overview

This application logs observations from an Ashtech Z-XII receiver. It records observations directly into the RINEX format. A number of optional outputs are possible. The raw messages from a receiver can be recorded. Observations can also be recorded in a format that is easily imported into numerical packages.

3.21.2 Usage

rtAshtech

Optional Arguments

Short Arg.	Long Arg.	Description
-h	-help	Print help usage
-v	-verbose	Increased diagnostic messages
-r	-raw	Record raw observations
-l	-log	Record log entries
-t	-text	Record observations as simple text files
-p	-port=ARG	Serial port to use
-o	-rinex-obs=ARG	Naming convention for RINEX obs files
-n	-rinex-nav=ARG	Naming convention for RINEX nav message files
-T	-text-obs=ARG	Naming convention for obs in simple text files

3.21.3 Examples

```
> rtAshtech -p /dev/ttyS1
```

```
> rtAshtech -o "minute\%03j\%02H\%02M.\%02yo"
```

3.21.4 Notes

Only works on UNIX systems with POSIX compliant serial ports.

3.22 *timeconvert*

3.22.1 Overview

This application allows the user to convert among time formats associated with GPS. Time formats include: civilian time, Julian day of year and year, GPS week and seconds of week, Z counts, and Modified Julian Date (MJD).

3.22.2 Usage

Optional Arguments

Short Arg.	Long Arg.	Description
-d	-debug	Increase debug level
-v	-verbose	Increase verbosity
-h	-help	Print help usage
-c	-calendar=TIME	"Month(numeric) DayOfMonth Year"
-r	-rinex=TIME	"Month(numeric) DayOfMonth Year Hour:Minute:Second"
-R	-rinex-file=TIME	"Year(2-digit) Month(numeric) DayOfMonth Hour Minute Second"
-y	-doy=TIME	"Year DayOfYear SecondsOfDay"
-m	-mjd=TIME	"ModifiedJulianDate"
-o	-shortweekandsow=TIME	"10bitGPSweek SecondsOfWeek Year"
-z	-shortweekandzcounts=TIME	"10bitGPSweek ZCounts Year"
-f	-fullweekandsow=TIME	"FullGPSweek SecondsOfWeek"
-w	-fullweekandzcounts=TIMEo	"FullGPSweek ZCounts"
-u	-unixtime=TIME	"UnixSeconds UnixMicroseconds"
-Z	-fullZcounts=TIME	"fullZcounts"
-F	-format=ARG	Time format to use on output
-a	-add-offset=NUM	add NUM seconds to specified time
-s	-sub-offset=NUM	subtract NUM seconds from specified time

3.22.3 Examples

```
> timeconvert -r "05 06 1985 13:50:02"
```

```

Month/Day/Year      5/6/1985
Hour:Min:Sec        13:50:02

Unix_sec Unix_usec	1151194150 0
FullZcount	187171182

3.22.4 Notes

3.23 *WhereSat*

3.23.1 Overview

This application uses input ephemeris to compute the predicted location of a satellite. The Earth-centered, Earth-fixed (ECEF) position of the satellite is reported. Optionally, the topocentric coordinates—azimuth, elevation, and range—can be generated. The user can specify the time interval between successive predictions. Also the output can be generated in a format easily imported into numerical packages.

3.23.2 Usage

Required Arguments

Short Arg.	Long Arg.	Description
-b	-broadcast=ARG	Specify a RINEX navigation file. The user may enter multiple files.
-p	-prn=NUM	Specify which SV to analyze.

Optional Arguments

Short Arg.	Long Arg.	Description
-h	-help	Generates help and usage.
-u	-position=ARG	Specify antenna position in ECEF (x,y,z) coordinates as "X Y Z". Used to give user-centered data (SV range, azimuth & elevation).
-s	-start=ARG	Specify time to begin analysis as "MO/DD/YYYY HH:MM:SS". The default is the end of the file.
-e	-end=ARG	Specify time to end analysis as "MO/DD/YYYY HH:MM:SS". The default is the beginning of the file.
-o	-output-filename=ARG	Outputs results to a MATLAB readable file.
-t	-time=NUM	Specify time increment for ephemeris calculation in seconds. Default is 900 (15 min.)

3.23.3 Examples

```
> WhereSat -b aira1720.06n -p 2 -u "918129.01 -4346070.45 803.18"
-s "06/21/2006 17:00:00" -e "06/21/2006 20:00:00" -t 1800
```

```
Antenna Position: 918129 -4.34607e+06 803.18
Navigation File: aira1720.06n
Start Time:      06/21/2006 17:00:00
End Time:        06/21/2006 20:00:00
PRN:             2
```

```
Prn 2 Earth-fixed position and clock information:
```

Date	Time(UTC)	X (meters)	Y (meters)	Z (meters)
